

The Earth in 2050

There is no doubt that Earth in 2050 will be very different from now, from rising global issues to innovations, which will not be the same as today.

Global issues will transform significantly. One thing for sure is that the population will increase at an alarming rate making houses more expensive to live in since there won't be much land left. Another thing is that temperatures are rising melting away the ice in the Arctic. Earth may be inhabitable from all the carbon dioxide and other toxic chemicals released into the air.

Unless the world tries to solve these issues by coming up with effective global improvements, the earth is going to be a disaster. We should use clean energy to generate electricity. Examples of clean energy are wind power produced by wind turbines, solar power from solar panels and hydroelectric power from steam power generators. A way to fix overpopulation is by living in the space. Let's imagine living on the moon seeing the whole world while we stand in one place.

I am also really excited about what new innovations scientists are going to create. I am pretty sure they are going to make solar-powered cars that we could drive for miles without using any fuel.

Robotic technology has been rapidly developing. In just a couple of decades your children will be learning with a human-looking child robot. You also won't need to hire a maid to do the housework because you could just purchase a personal robot maid.

In conclusion, many things will happen in 2050.
